Physical Mathematics and The Fine-Structure Constant

Michael A. Sherbon

Case Western Reserve University Alumnus
michael.sherbon@case.edu

Abstract

Research into ancient physical structures, some having been known as the seven wonders of the ancient world, inspired new developments in the early history of mathematics. At the other end of this spectrum of inquiry the research is concerned with the minimum of observations from physical data as exemplified by Eddington’s Principle. Current discussions of the interplay between physics and mathematics revive some of this early history of mathematics and offer insight into the fine-structure constant. Arthur Eddington’s work leads to a new calculation of the inverse fine-structure constant giving the same approximate value as ancient geometry combined with the golden ratio structure of the hydrogen atom. The hyperbolic function suggested by Alfred Landé leads to another result, involving the Laplace limit of Kepler’s equation, with the same approximate value and related to the aforementioned results. The accuracy of these results are consistent with the standard reference. Relationships between the four fundamental coupling constants are also found.

Keywords: fine-structure constant; dimensionless physical constants; history of mathematics; golden ratio; history of physics; mathematical constants; fundamental constants

Subject Classification: PACS: 01, 02, 31.

Type (Method/Approach): Theoretical and Historical Inquiry.

1. Introduction

Natalie Paquette has stated that “Mathematicians discovered group theory long before physicists began using it. In the case of string theory, it is often the other way around. Physics has lent the dignity of its ideas to mathematics. The result is what Greg Moore has called physical mathematics.” [1, 2]. For an additional comprehensive overview of these results see the work of Terry Gannon [3]. Édouard Brézin is “… in agreement with Paquette. We should expect to see more new insights in mathematics emerging from the rich structure of physical problems.” [4]. Robbert Dijkgraaf states, “Mathematics has a long history of drawing inspiration from the physical sciences, going back to astrology, architecture and land measurements in Babylonian and Egyptian times.” [5]. From Arnold Sommerfeld in the history of physics [6], Stephen Brush writes that in 1916 “Arnold Sommerfeld generalized Bohr’s model to include elliptical orbits in three dimensions. He treated the problem relativistically (using Einstein’s formula for the increase of mass with velocity), … According to historian Max Jammer, this success of Sommerfeld’s fine-structure formula “... served also as an indirect confirmation of Einstein’s relativistic formula for the velocity dependence of inertia mass.” [7]. The electromagnetic coupling constant determining the strength of its interaction is the fine-structure constant \( \alpha = \frac{e^2}{\hbar c} \) in cgs units with the elementary charge \( e \), the reduced Planck’s constant \( \hbar = \frac{h}{2\pi} \) and the speed of light \( c \). As Max Born wrote, “It is clear that the explanation of this number must be the central problem of natural philosophy.” [8]. This was a view also shared by Wolfgang Pauli [9, 10].

2. Eddington’s Principle

Regarding relativity and quantum mechanics in Dirac’s work on the electron spin, “It was not till the initiative inspired by Dirac’s equation that Eddington had the notion of a bridge between the theories. Comparing treatments would give numerical values for certain physical constants.” [11]. Helge Kragh writes, “Like many contemporary physicists, Dirac believed that ultimately \( \alpha \) should be explainable by physical theory. As late as 1978, he wrote: ‘The problem of explaining this number [fine-structure constant] is still completely unsolved. … I think it is perhaps the most fundamental unsolved problem of physics at the present time, and I doubt very much whether any really big progress will be made in understanding the fundamentals of physics until it is solved.’” [12]. Helge Kragh also states that, “By 1929 the fine-structure constant was far from new, but it was only with Eddington’s work that the dimensionless combination of constants of nature was elevated from an empirical quantity appearing in spectroscopy to a truly fundamental constant.” [12]. In addition, Kragh states, “He was also the first to argue that \( \alpha \) was of deep cosmological significance and that it should be derivable from fundamental theory.” [13]. Eddington asked himself what the minimum amount of data from observation was required for a physical theory. This led to Eddington’s Principle from which he maintained that the value of the inverse fine-structure constant was 136, which he later changed to 137. Eddington’s Principle is defined as: “All the quantitative propositions of physics, that is, the exact values of the pure numbers that are constants of science, may be deduced by logical reasoning from qualitative assertions without making any use of quantitative data derived from observation.” [14].

3. Fine-structure constant

Nikos Salingaros says, “Eddington anticipated results of current interest. He discovered the Majorana spinors, and was responsible for the standard \( y^5 \) notation as well as the notion of chirality. Furthermore, Eddington defined Clifford algebras in eight and nine dimensions which are now appearing in grand unified gauge and supersymmetric theories. A point which Eddington cleared up, yet is still misunderstood, is that the Dirac algebra corresponds to a five-dimensional base space.” [15]. In addition, “Eddington did not clearly anticipate current physical supersymmetry theories. He did sense that a larger Clifford algebra would be useful in a symmetrical description of nature, and in this aspect he was entirely correct.” [15], also see [16]-[19]. As the use of advanced algebras grew in the study of symmetry another development of interest happened in 1974 when Howard Georgi and Sheldon Glashow proposed SU(5) as “... the gauge group of the world — that all elementary particle forces (strong, weak, and electromagnetic) are different manifestations of the same fundamental interaction involving a single coupling strength, the fine-structure constant.” [20]. As Giora Shaviv points out “… if you consider a symmetric matrix in \( 16 = 4 \times 4 \) dimensions, then the number of independent
terms in this matrix is ... 136." [21]. Eddington: 16 + (162 − 16)/2 = 256 − 120 = 136. Inverse fine-structure constant is a root of:

\[ x^4 − 136x^3 − 136x^2 − 818x + 1 = 0. \]  \hspace{1cm} (1)

This equation gives a value of for \( x \) as \( a^{-1} \approx 137.035 \, 999 \, 168 \). The inferred value for the inverse fine-structure constant determined from quantum electrodynamics theory and experiment with the least standard uncertainty in CODATA results is \( a^{-1} \approx 137.035 \, 999 \, 160 \) (33) [22]. The other root of the equation is approximately 1/818 and 818 = (136 + 1/3)6 = (4 x 136) + (2 x 137).

In William Eisen's research on the geometry of the “Golden Apex of the Great Pyramid,” his interpretation involving Euler's identity, \( \exp(i\pi) + 1 = 0 \) shows a drawing of four curves of \( e^x \) from \( x = 0 \) to \( x = \pi \), one curve on each side and labelled the “Graphical Representation of the Exponential Function to the Base \( e \)” [23]. Dividing the side lengths of the Great Pyramid by \( \pi \) lengths results in a small central square called the Golden Apex, the geometry associated with the fivefold symmetry of the Great Pyramid and the four forces of nature [24].

Golden Apex A:

\[ A = e^\pi − 7\pi − 1 ≈ \sqrt{2}/3\pi ≈ \varphi^2/2K = 3/20. \]  \hspace{1cm} (2)

A is the side length of the Golden Apex square. \( \sqrt{A} \approx e/7 \) and \( A + 1 = e^\pi − 7\pi ≈ R \), radius of the regular heptagon with side equal to one, \( R − 1 = 2\sin(\pi/7) \). The \( \sin(2\pi A) \approx \varphi/2 \), where \( \varphi \) is the golden ratio [24]. Also related, \( \sqrt{A} + 1 ≈ K/2\pi \), see references in [24]. The polygon circumscribing constant is \( K = 2\tan(3\pi/7) \approx \varphi^2/2A \) [25]. The Golden Apex A and the golden ratio relate simple approximations involving the four fundamental coupling constants:

\[ A ≈ \sqrt{\varphi/3}/\ln \alpha^{-1} ≈ 2\sqrt{3\varphi}\alpha_w ≈ \alpha_s\sqrt{\varphi} ≈ 7\sqrt{3\varphi}/\ln \alpha_g^{-1}, \]  \hspace{1cm} (3)

where \( \alpha_w \) is the weak nuclear force coupling constant, \( \alpha_s \) is the strong nuclear force coupling constant and \( \alpha_g \) is the gravitational coupling constant [26]. The inclusion of the four fundamental coupling constants in the Golden Apex design is part of the symbolic interpretation presented by William Eisen [23]. Other brief approximations involving the four fundamental coupling constants include: \( A ≈ 4\pi\alpha \approx \alpha_w /\sin^2\theta_w ≈ \pi\alpha_s \) /4 \( \approx K\sqrt{\pi}/\ln \alpha_g^{-1} \). The Weinberg angle, \( \sin^2\theta_w \approx \cot(3\pi/7) \approx \sqrt{7} \). The Golden Apex A has more relatively simple approximations:

\[ A ≈ 7\sqrt{\alpha} / 4 ≈ \lambda\sqrt{7\alpha} ≈ 7\alpha\sqrt{K} \approx 7\sqrt{\alpha / \varphi} / \pi, \]  \hspace{1cm} (4)

with the fine-structure constant and the related Laplace limit of Kepler's equation, \( \lambda \) [27, 28]. Raji Heyrovská found that the Bohr radius was divided by the golden ratio into two different sections giving \( a^{-1} \approx (360/\varphi^3) − (2/\varphi^3) \) [29], with a difference from experiment possibly due to the g-factors of the electron and proton [30]. Her equation was then extended with the Golden Apex A and the polygon circumscribing constant \( K \) [31]. Related to Golden Apex geometry [27], 667 − 178 − 49 = 440, \( 4 + 49 + 49 + 178 = 280 \), 667 + 136 − 137 = 666 and \( 4 + 49 + 667 = 280 + 440 = 720 \) [24]. Fine-structure constant \( \alpha \approx A/\pi, \) \( x \) is a root of:

\[ 4x^3 − 49x^2 − 667x − 178 = 0. \]  \hspace{1cm} (5)

This equation gives a value for \( a^{-1} \approx 137.035 \, 999 \, 168 \). Another approximation involving the golden ratio is also related to Eq. (1), recalling some of Eddington's work, \( 136 + 136 + 48 = 440 − 120 \) and \( 280 = 136 + 144 \). Also, \( 346 − 280 − 36 = 30 \), \( 280 − 30 = 250 \), \( 3 \times 36 = 108 \), \( 3 \times 48 = 144 \), \( 108^2 + 144^2 = 180^2 \) [24]. This polynomial equation gives a value for the inverse fine-structure constant \( a^{-1} \approx 137.035 \, 999 \, 168 \) and \( \alpha^{-1} \approx \varphi x \), where \( x \) is a root of:

\[ 3x^4 − 250x^3 − 346x^2 + 48x − 36 = 0. \]  \hspace{1cm} (6)
In 1939 Alfred Landé, who found the Landé g-factor of the electron, stated that the \( \sinh(2\pi) \) was significant to an understanding of the fine-structure constant [32, 33]. From the Golden Apex view, \( \alpha^{-1} \approx \lambda \sinh(2\pi)/KA \approx \sinh(2\pi)/\lambda \sqrt{K} \) and \( \alpha \sinh(2\pi) \approx \tan^{-1}(4/\pi)/\tan^{-1}(1/2) \), base angle of the physical structure defining the Golden Apex \( A \) divided by the ancient 'golden angle' [24, 31]. Another Landé inspired approximation of \( \alpha \sinh(2\pi) \) is a root of a cubic equation. The root of this cubic equation divided into \( \sinh(2\pi) \) gives a value for \( \alpha^{-1} \approx 137.035 \ 999 \ 168 \).

\[
33x^3 - 122x^2 + 377x - 517 = 0, \quad (7)
\]

with Fibonacci numbers, 517 – 377 = 140, 377 – 137 = 240, 720 – 377 = 344 and 89 = 122 – 33 [24]. Also, 818 – 440 – 377 = 137 – 136. Related to Alfred Landé again is the Laplace limit of Kepler’s equation, \( \lambda \approx A/\sqrt{\alpha} \approx \varphi \sqrt{A/R} \) [28] and \( \pi / \varphi^2 \approx \sqrt{1 + \lambda^2} \), where \( \sqrt{1 + \lambda^2} = \mu \) is the real fixed point of the hyperbolic cotangent related to the anomalous magnetic moment of the electron: \( \sinh(\mu) \approx \lambda^{-1} \) and \( \alpha \sinh(2\pi) \approx 2 \mu \sqrt{\lambda} \) [34]. For the value of \( \alpha^{-1} \approx 137.035 \ 999 \ 168 \) as the inverse fine-structure constant: \( \alpha^{-1} \approx x/\lambda \), where \( x \) is a root of:

\[
5x^3 - 455x^2 + 86x - 375 = 0. \quad (8)
\]

Related, 455 – 375 = 360 – 280, 455/5 = 5 + 86, 375 – 136 – 86 = 153 and 153/136 = 9/8, from the source geometry of the physical structure determining the Golden Apex [27]. Additionally, 137 + 137 = 360 – 86, and 455 – 375 = 440 – 360. Also related, 360 + 360/5 = 432 = 360\( \pi / \varphi^2 \approx \varphi \sinh(2\pi) \). With hyperbolic functions, \( \varphi^{-1} \approx \sinh^{-1} \lambda \approx \cosh^{-1} \mu \) and \( \varphi \approx \sinh^{-1}(2\mu) \). The dimensionless proton-electron mass ratio is \( m_p/m_e \approx \varphi^4 \sinh(2\pi) \) and \( \varphi^4 = A + A^{-1} \approx 7 – A \).

### 4. Squaring the circle

Squaring the circle has been a metaphor for the effort to unify relativity and quantum theory [35]. Related to the squaring of the circle are more approximations involving the four fundamental coupling constants. The proportion significant to ‘squaring the circle’ in the classical tradition was found by John Michell and presented in his study of what he named the Cosmological Circle: \( 3/11 \approx \sqrt{\varphi - 1} \approx \sqrt{\varphi \alpha / \alpha_w} \approx \alpha_s \sqrt{\varphi S} \approx \sqrt{\varphi / \ln(\ln \alpha_w^{-1})} \) [31]. \( S \) is the silver constant from the regular heptagon [34]. \( S = 4 \sin^2(2\pi/7) = 2 + 2 \sin(2\pi/7) = 2 + \sqrt{S/R} \), the regular heptagon and the golden ratio are both closely associated with the classical geometry of ‘squaring the circle.’ \( S = \sqrt{\pi/2A} \approx 4/\lambda \approx 2\varphi \) and \( S^{-1} \approx \tan(\pi^{-1}). \)

Also, \( 3/11 = 120/440 \approx A/2A \approx A/\varphi S \approx \sqrt{\alpha / 2A} \approx \sqrt{\varphi A \varphi S} \approx 7.63 \approx 280 \) and the apex angle is 76.3° [24]. The Golden Apex \( A \approx \pi / (3 \times 7) \approx 2\pi \alpha S \) [28, 31]. The conceptual structure defining the Golden Apex has a significant relationship to advanced algebras, modular forms and fundamental physics [27].

### 5. Conclusion

These calculations of the inverse fine-structure constant are aimed toward a fuller explanation of the fundamental physics and the interrelated mathematics. As Albert Einstein noted, “Our experience up to date justifies us in feeling sure that in Nature is actualized the ideal of mathematical simplicity. It is my conviction that pure mathematical construction enables us to discover the concepts and the laws connecting them which give us the key to the understanding of the phenomena of Nature.” [36]. Besides Eddington, Einstein’s view in this regard was also shared most notably by Paul Dirac [37]. Natalie Paquette, quoted in the introduction, concludes her article with, “If mathematics and physics are in so many respects in equipoise, then the differences between them may be less a matter of their content than their technique; and that, in the end, they serve to show that there is only one reality to which they both appeal.” [1].
